- Product with CMOS output active “H”, Nch open drain output active “H”

During charging in the normal status, any of battery voltages exceeds overcharge detection voltage (V_{CU}), and this status is maintained for overcharge detection delay time (t_{CU}) or longer, CO gets “H”. This is overcharge status. Connecting an FET to the CO pin enables charge-control and the second protect.

In this case, the IC maintains the overcharge status until all battery voltages decreases, to the overcharge hysteresis voltage (V_{CD}) from the overcharge detection voltage (V_{CU}).

- Product with CMOS output active “L”, Nch open drain output active “L”, Pch open drain output active “L”

During charging in the normal status, any of battery voltages exceeds overcharge detection voltage (V_{CU}), and this status is maintained for overcharge detection delay time (t_{CU}) or longer, CO gets “L”. This is overcharge status. Connecting an FET to the CO pin enables charge-control and the second protect.

In this case, the IC maintains the overcharge status until all battery voltages decreases, to the overcharge hysteresis voltage (V_{CD}) from the overcharge detection voltage (V_{CU}).

2. Delay Circuit

The delay circuit rapidly charges the capacitor connected to the delay capacitor connection pin up to a specified voltage when the voltage of one of the batteries exceeds the overcharge detection voltage (V_{CU}). Then, the delay circuit gradually discharges the capacitor at 100 nA and inverts the CO output when the voltage at the delay capacitor connection pin goes below a specified level. Overcharge detection delay time (t_{CU}) varies depending upon the external capacitor.

Each delay time is calculated using the following equation.

$$t_{CU}[s] = \text{Delay Coefficient} \begin{matrix} \text{Min.} & \text{Typ.} & \text{Max.} \\ (10, & 15, & 20) \end{matrix} \times C_{ICT} [\mu F]$$

Because the delay capacitor is rapidly charged, the smaller the capacitance, the larger the difference between the maximum voltage and the specified value of delay capacitor pin (ICT pin). This will cause a deviation between the calculated delay time and the resultant delay time. Also, delay time is internally set in this IC to prevent the CO output from inverting until the charge to delay capacitor pin is reached to the specified voltage. If large capacitance is used, output may be enabled without delay time because charge is disabled within the internal delay time.

Please note that the maximum capacitance connected to the delay capacitor pin (ICT pin) is 1 μF .

■ Precautions

- This IC charges the delay capacitor through the delay capacitor pin (ICT pin) immediately when the voltage of one of batteries V1 to V4 reaches the overcharge voltage. Therefore, setting the resistor connected to the VCC pin to any value greater than the recommended level causes a reduction in the IC power supply voltage because of charge current of the delay capacitor. This may lead to a malfunction. Set up the resistor NOT to exceed the typical value. If you change the resistance, please consult us.
- DO NOT connect any of overcharged batteries. Even if only one overcharged battery is connected to this IC, the IC detects overcharge, then charge current flows to the delay capacitor through the parasitic diode between pins where the battery is not connected yet. This may lead to a malfunction. Please perform sufficient evaluation in the case of use. Depending on an application circuit, even when the fault charge battery is not contained, the connection turn of a battery may be restricted in order to prevent the output of CO detection pulse at the time of battery connection.

- In this IC, the output logic of the CO pin is inverted after several milliseconds of internal delay if this IC is under the overcharge condition even ICT pin is either "V_{SS}-short circuit," "V_{DD}-short circuit" or "Open" status.
- Any position from V1 to V4 can be used when applying this IC for a one to three-cell battery. However, be sure to short circuit between pins not in use (SENSE-VC1, VC1-VC2, VC2-VC3, or VC3-VSS).
- The application conditions for the input voltage, output voltage, and load current should not exceed the package power dissipation.
- Do not apply an electrostatic discharge to this IC that exceeds the performance ratings of the built-in electrostatic protection circuit.
- SII claims no responsibility for any and all disputes arising out of or in connection with any infringement of the products including this IC upon patents owned by a third party.
